Plates and screws for internal fracture fixation'

Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

EP 0 530 585 B1

Description

1. Field of the invention

The present invention relates to bone screws and plates used for internal fixation of bone fractures, which are produced from a resorbable polymer and/or resorbable polymer-resorbable glass/ceramic composite which is finally resorbed and/or incorporated in the tissues.

Bone fractures are usually reduced using temporary internal and/or external fixation devices such as screws, plates, wires and external fixators.

2. Description of the Prior Art

Commonly used osteosynthesis devices are produced from metals, mainly from medical grade stainless steel, pure titanium or titanium alloys.

Metallic implants used successfully for fracture reduction also have certain disadvantages. They show large differences in Young's modulus as compared with moduli of bones, frequently undergo in vivo corrosion, and have to be removed after the bone fracture is healed.

To avoid these problems, numerous efforts have been undertaken to develop internal fixation devices which do not have to be removed from the implantation site, do not corrode, have Young's moduli close to those of the bone, transfer increasing load to the bone, and yet assure adequate fixation of bony fragments. Materials which are considered as candidates for such implants are bioresorbable polymers and eventually resorbable polymers reinforced with resorbable glasses and/or ceramics.

The use of resorbable polymers for construction of internal fixation devices is the subject of numerous publications, e.g.:

Kulkarni RK, Pani KC, et al (1969), Polylactic acid for surgical implants, Arch Surg 93, 839;
Cutright DE, Hunsuck EE, et al (1971), Fracture reduction using a biodegradable material, polylactic acid, J Oral Surg 29, 393;
Vert M, Chabot F, et al (1981), Bioresorbable plastic materials for bone surgery, in Macromolecular Biomaterials, CRC Press, Boca Raton, 119;
Tunc R (1990) Absorbable bone plate, US Patent No. 4,905,680, March 6, 1990;
Matsusue Y, Yamamuro T, et al (1991), Biodegradable screw fixation of rabbit tibia proximal osteotomies, J Appl Biomater 2,1;
One publication of Leenslag JW, Pennings AJ, et al (1987), Plates and screws for internal fracture fixation, Biomaterials 8, 70, discloses an absorbable bone screw comprising a threaded shaft portion for insertion into bone, and a head portion for rigid connection in the screw hole of a bone plate, said head portion being at least partly conical tapering

towards said shaft portion.

The main drawbacks of resorbable polymeric screws and plates developed at present are their relatively poor mechanical properties, and frequently, early loss of stability of fracture fixation. The latter is mainly observed with implants which are produced using methods which lead to at least partial orientation of a polymer. This seems to be due to loosening of the contact between the screw head and the plate hole, resulting from nonuniform swelling of the fixation elements in the body fluids, and the premature erosion of the screw thread, which in the majority of designs is a copy of the metallic screw thread.

Attempts have been made to protect against loosening of the contact between the screw head and the plate hole by welding both elements together. This technique is not an optimal one, however, as it changes the structure of a polymer in the heated zone, leading to thermal degradation of a polymer in the heat exposed area, and consequently, to a premature in vivo degradation of the welded area. It may also cause tissue necrosis due to the action of heat generated upon welding.

3. Summary of the Invention

The present invention provides a resorbable bone screw as defined in Claim 1 and a bone plate system as defined in dependent Claim 10 which allows the avoidance of the premature loosening of stability of the fracture fixation.

The contacting surfaces of the screw head and the plate hole are designed in such a way that after exposing the implants to the body fluids, the self-locking of the screw head in the plate hole is further enhanced.

This property has been achieved by constructing the screw head with a three-dimensionally structured, e.g. corrugated or serrated outer surface contacting the similarly structured surface of the plate hole.

Preferably the three-dimensional structure consists of at least two corrugations or serrations running around the outer surface of the head portion. The corrugated and/or serrated surface can have a symmetric and/or an asymmetric arrangement of corrugations/serrations. The angle between two consecutive corrugations/serrations should be in the range of 5° to 175°, and preferably 30° to 130°. The head portion of the bone screw according to the invention is preferably of conical or convex shape matching appropriate screw holes in the bone plate having a conical or concave shape, whereby the diameter of the screw hole is diminishing towards to bone contacting face of the plate.

Corrugations can run straight along the head, they can be of symmetrical, asymmetrical or spiral shape or they can combine these features.

The outer surface of the screw head can either be covered fully with corrugations or can be only partially covered by it, e.g. only in the upper, enlarged part of the screw head.

The dimensions of the corrugations/serrations will depend on the overall dimensions of the screw/plate system, but in general they will incise 1 to 50 % of the screw head and preferably 5 to 10% of the screw head. The crest of the corrugations/serrations will be equal and/or 1 to 20 % thinner and preferably 5 to 10 % thinner than the crest of the screw head.

A suitable bone plate to be used together with the bone screw according to the invention may be made of the same or a similar resorbable polymer and/or resorbable polymer-resorbable glass/ceramic composite as the bone screw. The inner surface of the screw holes is provided with a three-dimensional structure corresponding to the three-dimensional structure on the outer surface of the head portion of the bone screw so that self-locking of the two three-dimensional structures (screw head/plate hole) occurs.

In a preferred embodiment of the bone plate it is provided with a continuous reinforcing bar portion running along the axis of the bone plate and accommodating the screw holes. The reinforcing bar portion is located at the upper part of the bone plate and has a height profile which diminishes from the lateral plate edges towards the center where the screw holes are located. By means of this design the overall stiffness of the bone plate is increased at the same time saving a considerable amount of material (in the lateral edge region of the bone plate). The bone plate with its reinforcing bar portion can be manufacture from one single piece of material or alternatively from two pieces one inferior plate component (with a rectangular profile) and a superior reinforcing bar component (with a trapezoid profile).

The thickness of the bone plate as measured across the reinforcing bar portion is preferably at least 1.1 to 2.0 times bigger than the thickness of the plate measured at the side edges of the plate, and most preferably 1.2 to 1.5 times thicker than the side edges of the plate.

In a further preferred embodiment of the bone plate its lower bone-contacting surface is at least partially provided with a three-dimensional structure, consisting e.g. of surface irregularities in the form of conical micro-craters or pyramids. These when in contact with bone, will diminish the negative effect of the plate on the blood supply to the bone area under the plate. The three-dimensional structure at the bone-contacting surface of the plate may alternatively consist of undercuts, which preferably run parallel to its longitudinal axis.

The bone screw and plate of the present invention is fabricated from a resorbable polymer which can be processed into implants using injection-moulding, compression-moulding, extrusion and other techniques used for polymers processing. For certain applications the gel-processing will be preferable to melt-processing as it does not cause polymer degradation.

The dimensions of the screw and plate will depend on the areas of application (maxillofacial/small fragments/long bone/tendon surgery) and in general, are

similar to those of existing metallic devices.

When used in situations allowing accommodation larger implants, the implants of the invention will have dimension larger than conventional ones to compensate for differences in mechanical properties between metals and polymers.

The number of the corrugated/serrated screw holes in the plate is similar to that of metallic implants, although it may be necessary to increase the number of holes when the implant is used in the areas of increased load.

Implants of the invention are preferably produced from oriented or at least partially oriented resorbable polymers, which means that they will have a fibrillated structure, at least in the surface (skin) layer formed upon processing.

In a preferred embodiment of the invention the crest of the bone screw thread has 0.11 to 1.00 mm thickness, and preferably 0.12 to 0.50 mm thickness which is at least 0.01 to 5.00 times thicker than the crest of metallic cancellous/cortex bone screws, or standard metallic screws with metric (ISO) or English (ANSI) thread, and preferably 0.5 to 1.0 times thicker than the crest of such screws.

The use of a thread thickness typical for metallic screws in the resorbable screws, would result in premature erosion of the crests, and thus the loss of stability of bone fracture fixation.

The implants of the invention can be used in typical situations when bone screws and plates are used, but they can also be used for attachment of tendon to the bone in the case of tendon fracture (e.g. disrupted tendon of the rotator cuffs).

Typical resorbable polymers suitable for fabrication of the devices of the invention are listed in Table I. It should be stressed, however, that the table lists only commercially available polymers and is far from being complete.

TABLE I

Typical examples of resorbable materials for constructing the devices of the invention:

Polyhydroxyacids, e.g. poly(L-lactide), poly(D-lactide), poly(L/D-lactide), poly(L/DL-lactide), polyglycolide, copolymers of lactide and glycolide of various compositions, copolymers of said lactides and/or glycolide with other polyesters, copolymers of glycolide and trimethylene carbonate, polyhydroxybutyrate, polyhydroxyvalerate, copolymers of hydroxybutyrate and hydroxyvalerate of various compositions, polyorthoesters, polyanhydrides, polydioxanone, polydioxanedi-ones, polyesteramides, polymalic acid, polyesters of diols and oxalic and/or succinic acids, polyaminoacids, copolymers of amino acids and glutamic acid, polyamides, polycaprolactone, polycarbonates.

Preferred degradable polymers (homopolymers/copolymers) are polylactides, polyglycolide, poly-

dioxanone, poly/glycolide-co-trimethylene carbonate), poly(lactide-co-glycolide), and polyesteramides.

Molecular weight of resorbable polymers to be used for fabrication of devices of the invention should be in the range of 50.000 to 1.000.000 and preferably in the range of 120.000 to 600.000 (viscosity-average molecular weight) as calculated from the following formula:

$$[\eta] = 5.45 \times 10^{-4} M_v^{0.73}$$

These polymers can also be used with admixture of small amounts of tricalcium phosphate and/or hydroxyapatite, added to a polymer before processing.

4. Brief Description of the Drawings

The various features of novelty which characterize the invention are pointed out with particularity in the claims annexed to and forming part of this disclosure. For the better understanding of the invention, its operating advantages and specific objects attained by its use, reference should be had to the accompanying drawings, examples and descriptive matter in which are illustrated and described preferred embodiments of the invention.

In the drawings,

FIG. 1a is a side view of one of the embodiments of the bone screw of the present invention;

FIG. 1b is a partial side view of the head portion of the screw according to FIG. 1a;

FIG. 1c is a side view of a modified head portion of the bone screw of the present invention;

FIG. 2 is a perspective view of the bone plate with corrugated/serrated screw holes and reinforcing bar.

FIG. 3 is an enlarged partial view of a corrugated/serrated screw hole of the bone plate according to FIG. 2;

FIG. 4a is a cross-sectional view of the bone screw according to FIG. 1 fitting the bone plate according to FIG. 2;

Fig. 4b is a partial top view of the screw/bone-plate system according to FIG. 4a;

FIG. 5a is longitudinal section through a modified screw/bone plate system according to FIG. 4 with a three-dimensionally structured undersurface;

FIG. 5b is an enlarged detailed perspective view of the three-dimensional irregularities located at the undersurface of the bone plate according to FIG. 5a; and

Fig. 6 is a side view of another embodiment of the bone screw of the present invention;

5. Description of the Preferred Embodiments

The bone screw according to the invention and the corresponding bone plate are now further described by having reference to the drawings:

As shown in Fig. 1a the absorbable bone screw 10 according to the invention basically comprises a threaded shaft portion 1 with a pointed end 2, for insertion into bone and a head portion 3 for rigid connection in the screw hole of a bone plate. The diameter of the head portion 3 increases over the full length of the head portion 3 in the direction opposite to said shaft portion 1 such as to form a frustum of a cone. The outer surface of the head portion 3 is provided over its full circumference with a three-dimensional structure 4 forming a symmetric, corrugated surface. The elevations and depressions of the corrugations are running from the top of the head portion 3 (having a larger diameter of approximately 5 mm) to the lower part of the head portion 3 (having a smaller diameter of approximately 3 mm).

Figs. 1b and 1c are representing modifications of the three-dimensional structure 4 of the outer surface of the head portion 3 (Fig. 1b: asymmetric, corrugated surface/ Fig. 1c: spiral-shaped, corrugated surface). The thread 5 of the shaft portion 3 is provided with crests 6 having 0.2 mm thickness.

The corresponding bone plate 20 to be used with the bone screw 10 is shown in Fig. 2. It has a length of approximately 50 mm and a width of 7 mm. Its profile 11 is approximately rectangular in its inferior part (bone contacting side) and approximately trapezoidal in its superior part. Along its longitudinal axis 12 a plurality of screw holes 13 are located for receiving absorbable bone screws 10. The screw holes 13 have the shape of a frustum of a cone in order to match the correspondingly shaped head portion 3 of the bone screws 10 to be inserted therein. The larger diameter of the screw hole 13 of approximately 5 mm is located at the upper side of the bone plate 20 and the smaller diameter of the screw hole 13 of approximately 3 mm is located at the lower (bone-contacting) side of the bone plate 20. The resorbable plate 20 has a reinforcing bar portion 15 running longitudinally along the plate 20 and accommodating the screws holes 13. The thickness of the plate 20 as measured across the reinforcing bar portion 15 is 5 mm and the thickness of the plate 20 measured at the side edges of the plate 20 is 3 mm.

As shown in Fig. 3 the inner surface of the screw holes 13 is provided with a three-dimensional structure 14 corresponding to the three-dimensional structure 4 on the outer surface of the head portion 3 of the bone screws 10, so that self-locking of said two three-dimensional structures 4 and 14 occurs upon insertion of the bone screw 10 into the screw hole 13.

Fig. 4 shows in detail how the conical head portion 3 of

the bone screw 10 fits into the screw hole 13 of the bone plate 20 and interlocks with it in the interlocking zone 16. In order to facilitate insertion of the bone screw 10 a hexa-hole 17 is provided in the head portion 3.

In a preferred embodiment of the invention - represented in Figs. 5a and 5b - the lower surface 22 of the bone plate 20 is provided with a regular three-dimensional structure 21 consisting of conical elements 23 or pyramidal elements 24 designed to decrease the contact area between the plate 20 and the bone. The lower surface 22 of the bone plate 20 may be further provided with undercuts (not represented in the figure), preferably running parallel to its longitudinal axis.

In a further preferred embodiment of the invention - represented in Fig. 6 - the outer surface of the conical head portion 3 of the bone screw 10 is provided only in its upper part with a three-dimensional structure 4 in the form of corrugations running around the full circumference of the head portion 3.

Claims

1. An absorbable bone screw (10) comprising a threaded shaft portion (1) for insertion into bone and a head portion (3) for rigid connection in the screw hole of a bone plate, said head portion (3) being at least partly conical tapering towards said shaft portion (1)
characterized in that
the outer surface of the conical part of said head portion (3) is provided with a three-dimensional structure (4).
2. An absorbable bone screw (10) according to claim 1, characterized in that the thread (5) of said shaft portion (1) is provided with crests (6) having a thickness in the range of 0.11 to 1.00 mm, preferably in the range of 0.12 to 0.50 mm.
3. An absorbable bone screw (10) according to claim 1 or 2, characterized in that said three-dimensional structure (4) is running essentially parallel to the axis of said screw (10).
4. An absorbable bone screw (10) according to claim 1 or 2, characterized in that said head portion (3) is convex.
5. An absorbable bone screw (10) according to one of the claims 1 - 4, characterized in that said three-dimensional structure (4) consists of corrugations or serrations running around said outer surface of said head portion (3).
6. An absorbable bone screw (10) according to one of the claims 1 - 5, characterized in that said three-dimensional structure (4) is limited to the upper part of said outer surface of said head portion (3).
7. An absorbable bone screw (10) according to one of the claims 1 - 6, characterized in that it comprises at least two corrugations or serrations.
8. An absorbable bone screw (10) according to one of the claims 1 - 7, characterized in that it is produced from oriented or at least partially oriented resorbable polymers.
9. An absorbable bone screw (10) according to claim 8, characterized in that at least the surface layer of said bone screw (10) has a fibrillated structure.
10. Combination of an absorbable bone screw (10) according to one of the claims 1 - 9 with an absorbable bone plate (20),
characterized in that
said absorbable bone plate (20) has an upper surface, a lower surface (22) for contacting bone, a longitudinal axis (12) and a plurality of screw holes (13) located along said axis (12) for receiving each an absorbable bone screw (10), and
that the inner surface of said screw holes (13) is provided with a three-dimensional structure (14) corresponding to said three-dimensional structure (4) on said outer surface of said head portion (3) of said bone screw (10) so that interlocking can take place in the interlocking zone (16).
11. Combination according to claim 10, characterized in that said absorbable bone plate (20) comprises at least one reinforcing bar portion (15) running along said axis (12) and accommodating the screw holes (13).
12. Combination according to claim 10 or 11, characterized in that said lower surface (22) of said bone plate (20) is at least partially provided with a three-dimensional structure (21).
13. Combination according to claim 12, characterized in that said three-dimensional structure (21) comprises conical elements (23) or pyramidal elements (24) designed to decrease the contact area between said plate (20) and the bone.
14. Combination according to one of the claims 10 - 13, characterized in that said lower surface (22) of said bone plate (20) is provided with undercuts, which preferably run parallel to said longitudinal axis (12).
15. Combination according to one of the claims 10 - 14, in particular for internal fixation of bone fractures and for tendon-to-bone attachment,
characterized in that
said three-dimensional structures (14,4) of said screw holes (13) and of said bone screws (10) are matched to provide self-locking of said three-dimensional structures (14,4) in their interlocking

zone (16).

Patentansprüche

1. Absorbierbare Knochenschraube (10), die einen gewindeten Schaftteil (1) zur Einführung in den Knochen und einen Kopfteil (3) zur starren Befestigung in der Schraubbohrung einer Knochenplatte umfaßt, wobei dieser Kopfteil (3) zumindest teilweise zu diesem Schaftteil (1) hin kegelförmig verjüngt ist, dadurch gekennzeichnet, daß die Außenfläche des kegelförmigen Teils dieses Kopfteils (3) eine dreidimensionale Struktur (4) aufweist. 5 10 15
2. Absorbierbare Knochenschraube (10) gemäß Anspruch 1, dadurch gekennzeichnet, daß die Windung (5) dieses Schaftteils (1) Spitzen (6) mit einer Dicke zwischen 0,11 und 1,00 mm und vorzugsweise zwischen 0,12 und 0,50 mm aufweist. 20
3. Absorbierbare Knochenschraube (10) gemäß Anspruch 1 oder 2, dadurch gekennzeichnet, daß diese dreidimensionale Struktur (4) im wesentlichen parallel zur Achse dieser Schraube (10) verläuft. 25
4. Absorbierbare Knochenschraube (10) gemäß Anspruch 1 oder 2, dadurch gekennzeichnet, daß dieser Kopfteil (3) konvexförmig ist. 30
5. Absorbierbare Knochenschraube (10) gemäß einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß die dreidimensionale Struktur (4) aus Wellungen oder Zahnungen besteht, die um die Außenfläche des Kopfteils (3) verlaufen. 35
6. Absorbierbare Knochenschraube (10) gemäß einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß die dreidimensionale Struktur (4) auf den oberen Teil der Außenfläche des Kopfteils (3) begrenzt ist. 40
7. Absorbierbare Knochenschraube (10) gemäß einem der Ansprüche 1 bis 6, dadurch gekennzeichnet, daß sie zumindest zwei Wellungen oder Zahnungen umfaßt. 45
8. Absorbierbare Knochenschraube (10) gemäß einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß sie aus ausgerichteten oder zumindest teilweise ausgerichteten resorbierbaren Polymeren besteht. 50
9. Absorbierbare Knochenschraube (10), gemäß Anspruch 8, dadurch gekennzeichnet, daß zumindest die Oberschicht der Knochenschraube (10) eine fibrillierte Struktur aufweist. 55
10. Kombination aus einer absorbierbaren Knochenschraube (10) gemäß einem der Ansprüche 1 bis 9 und einer absorbierbaren Knochenplatte (20), dadurch gekennzeichnet, daß diese absorbierbare Knochenplatte (20) eine obere Fläche, eine untere Knochenkontaktfläche (22), eine Längsachse (12) und mehrere Schraubbohrungen (13) aufweist, die entlang der Achse (12) jeweils zur Aufnahme einer absorbierbaren Knochenschraube (10) angebracht sind, und daß die Innenfläche der Schraubbohrungen (13) eine dreidimensionale Struktur (14) aufweist, die der dreidimensionalen Struktur (4) an der Außenfläche des Kopfteils (3) der Knochenschraube (10) entspricht, so daß sie im Greifbereich (16) ineinandergreifen können.
11. Kombination gemäß Anspruch 10, dadurch gekennzeichnet, daß die absorbierbare Knochenplatte (20) zumindest einen verstärkenden Stiffteil (15) umfaßt, der entlang der Achse (12) verläuft und in die Schraubbohrungen (13) paßt.
12. Kombination gemäß Anspruch 10 oder 11, dadurch gekennzeichnet, daß die untere Fläche (22) der Knochenplatte (20) zumindest teilweise eine dreidimensionale Struktur (21) aufweist.
13. Kombination gemäß Anspruch 12, dadurch gekennzeichnet, daß diese dreidimensionale Struktur (21) kegelförmige Elemente (23) oder pyramidenförmige Elemente (24) umfaßt, die so entworfen sind, daß die Kontaktfläche zwischen der Platte (20) und dem Knochen verringert wird.
14. Kombination gemäß einem der Ansprüche 10 bis 13, dadurch gekennzeichnet, daß die untere Fläche (22) der Knochenplatte (20) Querschnitte aufweist, die vorzugsweise parallel zur Längsachse (12) verlaufen.
15. Kombination gemäß einem der Ansprüche 10 bis 14, im besonderen zum inneren Festmachen von Knochenbrüchen und zur Befestigung von Sehnen an Knochen, dadurch gekennzeichnet, daß die dreidimensionalen Strukturen (14, 4) der Schraubbohrungen (13) und der Knochenschrauben (10) zusammenpassen, so daß eine Selbstsicherung der dreidimensionalen Strukturen (14, 4) im Greifbereich (16) gegeben ist.

Revendications

1. Vis pour os absorbable (10) comprenant une partie (1) en tige filetée pour insertion dans l'os et une partie de tête (3) en vue d'une liaison rigide dans le trou pour vis d'une plaque pour os, ladite partie de tête (3) étant au moins partiellement conique en se

rétrécissant en direction de ladite partie de tige (1), caractérisée en ce que la surface extérieure de la partie conique de ladite partie de tête (3) est dotée d'une structure tridimensionnelle (4).

2. Vis pour os absorbable (10) selon la revendication 1, caractérisée en ce que le filet (5) de ladite partie de tige (1) est dotée de crêtes (6) présentant une épaisseur située dans l'intervalle allant de 0,11 à 1,00 mm, et de préférence dans l'intervalle de 0,12 à 0,50 mm.
3. Vis pour os absorbable (10) selon la revendication 1 ou 2, caractérisée en ce que ladite structure tridimensionnelle (4) court essentiellement parallèlement à l'axe de ladite vis (10).
4. Vis pour os absorbable (10) selon la revendication 1 ou 2, caractérisée en ce que ladite partie de tête (3) est convexe.
5. Vis pour os absorbable (10) selon l'une des revendications 1 à 4, caractérisée en ce que ladite structure tridimensionnelle (4) est constituée d'ondulations ou de dentelures courant autour de ladite surface extérieure de ladite partie de tête (3).
6. Vis pour os absorbable (10) selon l'une des revendications 1 à 5, caractérisée en ce que ladite structure tridimensionnelle (4) est limitée à la partie supérieure de ladite surface extérieure de ladite partie de tête (3).
7. Vis pour os absorbable (10) selon l'une des revendications 1 à 6, caractérisée en ce qu'elle comprend au moins deux ondulations ou dentelures.
8. Vis pour os absorbable (10) selon l'une des revendications 1 à 7, caractérisée en ce qu'elle est produite à partir de polymères résorbables orientés ou au moins partiellement orientés.
9. Vis pour os absorbable (10) selon la revendication 8, caractérisée en ce qu'au moins la couche de surface de ladite vis pour os (10) présente une structure fibrillée.
10. Combinaison d'une vis pour os absorbable (10) selon l'une des revendications 1 à 9 avec une plaque pour os absorbable (20), caractérisée en ce que ladite plaque pour os absorbable (20) présente une surface supérieure, une surface inférieure (22) destinée à entrer en contact avec l'os, un axe longitudinal (12) et plusieurs trous pour vis (13) situés le long dudit axe (12) pour recevoir chacun une vis pour os absorbable (10), et en ce que la surface intérieure desdits trous pour vis (13) est dotée d'une structure tridimensionnelle (14) correspondant à ladite structure tridimensionnelle (4) de

ladite surface extérieure de ladite partie de tête (3) de ladite vis pour os (10), de sorte qu'un engrènement puisse avoir lieu dans la zone d'engrènement (16).

11. Combinaison selon la revendication 10, caractérisée en ce que ladite plaque pour os absorbable (20) comprend au moins une partie (15) en barre de renfort courant le long dudit axe (12) et logeant les trous pour vis (13).
12. Combinaison selon la revendication 10 ou 11, caractérisée en ce que ladite surface inférieure (22) de ladite plaque pour os (20) est au moins partiellement dotée d'une structure tridimensionnelle (21).
13. Combinaison selon la revendication 12, caractérisée en ce que ladite structure tridimensionnelle (21) comprend des éléments coniques (23) ou des éléments pyramidaux (24) conçus pour diminuer la superficie du contact entre ladite plaque (20) et l'os.
14. Combinaison selon l'une des revendications 10 à 13, caractérisée en ce que ladite surface inférieure (22) de ladite plaque pour os (20) est dotée de découpes, qui courent de préférence parallèlement audit axe longitudinal (12).
15. Combinaison selon l'une des revendications 10 à 14, en particulier pour l'immobilisation interne de fractures osseuses et pour la fixation d'un tendon à un os, caractérisée en ce que lesdites structures tridimensionnelles (14, 4) desdits trous pour vis (13) et desdites vis pour os (10) se correspondent pour fournir un autoblocage desdites structures tridimensionnelles (14, 4) dans leur zone d'engrènement (16).
